요 약. 본 연구는 진동 frequency에 대하여 양자역학적 계산 값과 분광학적 측정 값 사이에 최소의 오차를 나타내는 기저함수 세트를 찾고자 하는 것이다. 이를 위하여 3-chloro-1-butene의 세 가지 이형태체 모두에 대하여 42개의 기저함수 세트를 가지고 진동 frequency를 계산 하였고, 이 계산으로 얻은 frequency들을 실험적으로 측정된 값들과 비교하였다. 그 결과 BLYP/6-31G(d), BLYP/6-31G(d,3p), B3LYP/6-31G(d)가 최소의 오차를 나타낸을 알 수 있었다. 이 가운데 모든 기준 진동 frequency에 대하여서는 BLYP/6-31G(d)가 0.53%로 최소의 오차를 나타내었으며, BLYP/6-31G(d,3p)는 수소 원자와 관련된 기준 진동에 대하여 그리고 B3LYP/6-31G(d)는 보다 무거운 원자와 관련된 기준 진동에 대하여 각각 0.01%의 오차를 나타내었다. 또한 BLYP/6-31G(d,3p)와 B3LYP/6-31G(d)를 합동하는 기법을 사용하면 3-chloro-1-butene의 HE, ME, CIE 이형태체들의 모든 기준 진동에 대하여 각각 0.01, 0.16, 0.37%의 오차를 갖는 좋은 frequency 계산 값을 얻을 수 있었다.

주제어: 기저함수, 진동 frequency, 3-Chloro-1-butene, DFT 계산, 합동 기법

ABSTRACT. We have determined the basis sets which give the least errors between the calculated and the observed vibrational frequencies. On this purpose we have carried out frequency calculations for the all three conformers of 3-chloro-1-butene with forty-two basis sets and these calculated frequencies were compared with the observed ones. The basis sets which give the least errors are BLYP/6-31G(d), BLYP/6-31G(d,3p) and B3LYP/6-31G(d). The BLYP/6-31G(d) gives the least error as 0.53% for all of the fundamental frequencies and the BLYP/6-31G(d,3p) and B3LYP/6-31G(d) both give the least error of 0.01% for the fundamentals related hydrogen(s) and heavier atoms, respectively. Using the combining technique with the BLYP/6-31G(d,3p) and B3LYP/6-31G(d) we have obtained the errors of 0.01, 0.16 and 0.37% for all of the fundamentals of HE, ME and CIE conformers of 3-chloro-1-butene, respectively.

Keywords: Basis Set, Vibrational Frequency, 3-Chloro-1-Butene, DFT Calculation, Combining Technique

INTRODUCTION

With the availability of fast small computers and quantum mechanical calculation programs such as Gaussian-98,¹ it is now possible to carry out rela-

tively accurate calculations on molecular structure, conformational stability and vibrational frequencies. Even though the quantum mechanical calculations are very useful to predict the structural parameters and vibrational frequencies, the calculated frequen-

cies are considerably discrepant among those obtained by different methods.²⁻⁷ Therefore, some of scientists use the scaling factors to fit the theoretical frequencies to the observed frequencies for assigning the fundamental vibrational modes of molecules.^{4,8} And also some of scientist believe that the higher basis set may give the better frequencies and use the time consuming very high basis set such as MP2/6-311++G(d,p). But the results were not as satisfactory as expected.^{4,5,9-11}

Therefore, it is necessary to find the calculation method(s) that gives very close values to the observed vibrational frequencies. For this purpose we performed forty-two sets of frequency calculations employing BLYP, B3LYP and MP2 methods on 3-chloro-1-butene. Because the 3-chloro-1-butene gives frequencies from three kinds of conformations.⁴ Therefore, this molecule will be the one of the best molecule as the representative one to find the best basis set for vibrational frequency calculation. The results of this study are reported herein.

CALCULATIONS

In this study all the calculations were carried out using the Gaussian-98 program¹ using Gaussian-type functions. The energy minima with respect to the nuclear coordinates were obtained by the simultaneous relaxation of all the geometrical parameters of molecule using the gradient method of Pulay.¹² The frequency calculations were performed analytically for the optimized structures of the conformer with the double bond eclipsing the H₆ hydrogen atom (HE; Fig. 1) of 3-chloro-1-butene using the BLYP/6-31G and BLYP/6-311G basis sets, which are known as good methods for the frequency calculation², including twelve kinds of depolarization functions of (d), (d,p), (d,2p), (d,3p), (2d), (2d,p), (2d,2p), (2d,3p), (3d), (3d,p), (3d,2p) and (3d,3p), respectively. And then the + and ++ diffuse functions were employed at the level of BLYP/6-31G and BLYP/6-311G respectively with the depolarization functions of (d), (d,3p) and (2d) that gave the least discrepant frequency differences. Finally the three basis sets that gave the best results among thirty-six BLYP

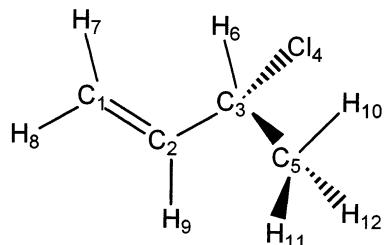

Fig. 1. Structural model and atom numbering of the HE form of 3-chloro-1-butene.

calculations have been taken and with these three basis sets the B3LYP and MP2 methods to obtain the optimized structures and frequencies for all three conformations of molecule have been performed. The percent discrepancies ($\Delta\%$) and standard deviations (σ) between the calculated and observed frequencies are listed in Table 1.

RESULT AND DISCUSSION

In Table 1 the $\Delta\%$ and σ the BLYP/6-31G(d) basis set gives best result with -0.53% discrepancy for all of the fundamental frequencies exception an asymmetric torsion for the HE form of 3-chloro-1-butene. The BLYP/6-31G(d,3p) and B3LYP/6-31G(d) give 0.01% of $\Delta\%$ for modes related to the hydrogen(s) and C=C stretch ('Light') and the heavier atoms and =CH bend (ν_{24}) which has more potential energy distribution value of CCl stretch⁴ ('Heavy'), respectively. The calculated and observed frequencies including differences ($\Delta\nu$ and $\Delta\%$) and standard deviations (σ) are listed in Table 2.

At the BLYP/6-31G(d) level calculation the D% excepting asymmetric torsion exist from -8.2 to 2.5% region and the total average error is -0.53%. And the average error for the 'Light' is 0.83% and for the one that related to the 'Heavy' is -4.09%. On the other hand the $\Delta\%$ at the BLYP/6-31G(d,3p) exist from -8.6 to 2.2% regions and the total average error is -1.29% and the average error for the 'Light' is 0.01% and for the 'Heavy' is -4.71%. And at the B3LYP/6-31G(d) the $\Delta\%$ exist from -1.9 to 5.3% region and the total average error is 2.84% and the average error for the 'Light' is 3.91% and for the 'Heavy' is 0.01%. These result clearly show that the

^a'All' refer to the all modes; 'Light' to the modes related to the H atom(s) and C=C stretch; 'Heavy' to the modes related to the heavier atoms and =CH bend (ν_{2a}). 'All', 'Light' and 'Heavy' all together not include the asymmetric torsion.

^bTaken from reference 4 and frequencies are in cm⁻¹.

^cFrequency difference between the calculated and observed frequencies as $\nu_{\text{calc.}} - \nu_{\text{obs.}}$.

^dPercent difference between the calculated and observed frequencies as $\frac{\nu_{\text{calc.}} - \nu_{\text{obs.}}}{\nu_{\text{obs.}}} \times 100\%$.

^eValues for the 'Light' are taken from BLYP/6-31G(d,3p) and those for the 'Heavy' from B3LYP/6-31G(d).

BLYP/6-31G(d,3p) gives the best frequencies for the ‘Light’ modes of HE conformer of 3-chloro-1-butene and the B3LYP/6-31G(d) does for the ‘Heavy’ ones. Therefore, with combining the frequencies from the BLYP/6-31G(d,3p) and the B3LYP/6-31G(d) for the ‘Light’ and ‘Heavy’ modes the total average error comes down from -1.29 and 2.84, respectively, to 0.01% with standard deviation 1.60%. With this error and standard deviation the calculated frequencies are in excellent agreement with the observed ones (*Table 2*).

With these BLYP/6-31G(d,3p) and B3LYP/6-31G(d) basis sets the frequency calculations for the higher energy conformers, the conformer with the double bond eclipsing the methyl group (ME) and the conformer with the double bond eclipsing the chlorine atom (CIE), of 3-chloro-1-butene also carried out and the results are listed in *Table 3* and *4*. The error, $\Delta\%$, of the ‘Light’ modes at the BLYP/6-31G(d,3p) obtained as -0.70 and -0.91% and the $\Delta\%$ of the ‘Heavy’ ones at the B3LYP/6-31G(d) as 0.65 and 0.34% for the ME and CIE form, respectively. By applying the combining method for the ME and CIE the $\Delta\%$ s for all modes come down to -0.16 and -0.37%, respectively. And we found most of the calculated frequencies with this combining method of all three conformers are in fairly good agreement with the observed ones within about $\pm 2\%$ errors with exception of those of CCC bend and two CCl bends of ME form. Therefore, the combining the frequen-

cies from BLYP/6-31G(d,3p) and B3LYP/6-31G(d) will be very useful to predict and assign the vibrational frequencies of molecules such as 3-chloro-1-butene. And it would be interest to reassign the CCC bend and two CCl bends of ME conformer of 3-chloro-1-butene using the frequencies from the B3LYP/6-31G(d) calculation.

The enthalpy differences, ΔH , among the HE, ME and CIE conformers of 3-chloro-1-butene in the vapor phase were also estimated from the BLYP/6-31G(d), BLYP/6-31G(d,3p) and B3LYP/6-31G(d). The ΔH values between the HE and ME form were obtained of 390 cm^{-1} (4.67 kJ/mol), 320 cm^{-1} (3.83 kJ/mol) and 353 cm^{-1} (4.22 kJ/mol) and those between the HE and CIE form were 685 cm^{-1} (8.19 kJ/mol), 600 cm^{-1} (7.18 kJ/mol) and 565 cm^{-1} (6.76 kJ/mol) with the HE being the most stable form from the BLYP/6-31G(d), BLYP/6-31G(d,3p) and B3LYP/6-31G(d), respectively (*Table 5*). These values are not significantly different from those obtained from the MP2/6-31G(d) and MP2/6-311++G(d).⁴

The structural parameters obtained from the BLYP/6-31G(d), BLYP/6-31G(d,3p) and B3LYP/6-31G(d) calculations are not significantly different from those experimentally obtained by electron diffraction (see *Table 6*).¹³ At the B3LYP/6-31G(d) level, the C-C and C-Cl bond lengths are about 0.6 and 1.8% shorter, respectively, than those at the BLYP/6-31G(d,3p) and closer to those of electron diffraction. The C-H bond lengths at the BLYP/6-

^cReference 13.

31G(d,3p) are about 0.5% longer than those at the B3LYP/6-31G(d). This could explain the reason why the B3LYP/6-31G(d) gives the better frequencies of fundamentals on heavier atoms and the BLYP/6-31G(d,3p) gives the better frequencies of fundamentals related to hydrogen(s).

By utilizing combining density functional calculations with the BLYP/6-31G(d,3p) and B3LYP/6-31G(d) basis sets, we have found an excellent agreement between the calculated vibrational frequencies and those obtained experimentally for the 3-chloro-1-butene. Therefore, it is believed that the

very high basis set, such as 6-311++G(d,3p), is not necessary to predict frequencies of this molecule and the combining method with the BLYP and B3LYP employing not a very high basis set, such as BLYP/6-31G(d,3p) and B3LYP/6-31G(d), can be valuable assigning the fundamental modes of 3-chloro-1-butene. And we found the combining technique presently discussed provides excellent estimates for the vibrational frequencies from the low to the high frequency modes of this molecule.
