요약. Sulfamethoxypyridazine, $C_{11}H_{12}N_4O_3S$ 의 결정 및 분자구조를 X-선 사진 회절법으로 구명하였다. 결정구조는 직접법으로 밝혀 최소자승법으로 정밀화 하였으며 2615 개의 회절 반점에 대한 촉증 R 값은 0.085이었다. 비대칭단위내의 분자 두개 A와 B는 S-N(2) 결합에 대한 형태가 서로 다른 형태 이성질체를 이루며, N(2A)H···N(3B)와 N(2B)H···O(1A) 수소 결합으로 연결되어 있다. 벤젠과 피리다진 고리의 면들이 이루는 각은 분자 A에서는 89° , 분자 B에서는 77° 이다.

ABSTRACT. The crystal structure of sulfamethoxypyridazine has been solved by the direct method and refined by least squares methods from three-dimensional data collected by the multiple-film technique to a final residual of 8.5 %. Two molecules (A and B) in one asymmetric unit are different each other in the conformation about S-N(2) bond, and are linked together by N(2A)H···N(3B) and N(2B)H···O(1A) S hydrogen bonds. Benzene and pyridazine rings make the angles of 89° and 77° for molecules A and B respectively.

INTRODUCTION

The analysis of X-ray crystal structures of sulfanilamide derivatives which usually have antibacterial activities has been undertaken by Professor C. H. Koo *et al.* Those are sulfapyridine¹, sulfisoxazole², sodium sulfisoxazole hexahydrate³, sulfaguanidine monohydrate^{4,5}, sulfadiazine⁶ and sulfadimethoxine⁷.

The crystal structure determination of sulfamethoxy pyridazine ($N'-(6\text{-methoxy-3-pyridazinyl})\text{sulfanilamide}$) has been attempted to compare its molecular structure with those of other

previously determined structures, especially conformation of sulfanilamide group, conformation about S-N(2) bond and interplanar angle of two aromatic rings. It is also of interest to study the hydrogen bonding systems involving amino and imino hydrogens.

The molecular conformations of two crystallographically independent molecules in one asymmetric unit are also compared each other.

EXPERIMENTAL

Transparent colorless crystals elongated along the α axis were obtained by slow evaporation of an acetone solution at room temperature.

Oscillation and Weissenberg photographs in-

* 이 논문은 1980년도 문교부 학술연구조성비에 의하여 연구되었음.

dicated the monoclinic space group $P2_1/C$. Unit cell parameters were measured from the $h0l$ and $hk0$ Weissenberg photographs calibrated with superimposed NaCl powder pattern as a standard using CuK α radiation. The crystal density was measured by the flotation method in a mixture of benzene and carbon tetrachloride. The crystal data are given in *Table 1*.

Intensity data were collected from equi-inclination Weissenberg photographs by use of multiple film method. The layers from $0kl$ to $7kl$ and from $h0l$ to $h1l$ were recorded. The approximate sizes of the crystals used for the data collection for the a and b axes were $0.5 \times 0.3 \times 0.2$ mm and $0.4 \times 0.2 \times 0.2$ mm respectively. The relative intensities were visually estimated by comparison with a calibrated density scale.

The intensities were corrected for spot-shape, Lorentz and polarization effects, and reduced to structure factors without corrections for absorption. The structure factors for various layers were placed on a common scale by correlating those of the equivalent reflections and then on an absolute scale by Wilson method⁸. A total of 2615 observed independent reflections were used in the structure analysis.

The structure was solved by MULTAN program⁹ with reflections whose E values are grea-

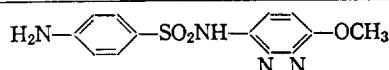

ter than 1.30. The set with the best figure of merit revealed the positions of all 38 non-hydrogen atoms among the fifty highest peaks on Fourier map. Structure factors based on 38 atoms with 2615 reflections gave an initial R of 0.33.

The structure was refined by standard least squares method. After six cycles of block-diagonal least squares refinements, the Fourier and difference Fourier syntheses were made to assign four nitrogen atoms in two pyridazine rings, and to locate hydrogen atoms. The atomic species of N(3), N(4), C(8) and C(9) could be readily discerned from comparison of the electron densities. The atoms that had the higher electron densities were assigned as N(3) and N(4) according to the method suggested by Stout and Jensen.¹⁰ The positions of the hydrogen atoms except H(N1) were located on the successive difference Fourier maps; they were included in the further refinements with fixed temperature factors equal to that of atom to which they were attached. Refinements were continued by several cycles of the full-matrix least squares using anisotropic structure factor calculations, and gave R value of 0.085 for all 2615 observed reflections with Hughes weighting scheme¹¹. The scattering factors for the sulfur, oxygen, carbon and nitrogen atoms were taken from Cromer and Waber¹² and those for hydrogen atom were assigned by Stewart, Davidson and Simpson.¹³ *Table 2* gives the final positional and thermal parameters of atoms*.

RESULTS AND DISCUSSION

The molecular conformation of two independent molecules are depicted in *Fig. 1* with atomic numbering. Two molecules are contained in each asymmetric unit and distinguished by

* Observed and calculated structure factors can be obtained from the authors.

Table 2. Final positional and thermal parameters for sulfamethoxypyridazine. The positional parameters are given as fractional coordinates ($\times 10^4$ for the non-hydrogen atoms and $\times 10^2$ for hydrogen atoms with the variances of atomic positions ($\times 10^4 \text{ \AA}^2$)). The anisotropic thermal parameters ($\times 10^4$) are defined as $\exp[-(\beta_{11}h^2 + \beta_{22}k^2 + \beta_{33}l^2 + 2\beta_{12}hk + 2\beta_{13}hl + 2\beta_{23}kl)]$. For each atom, the parameters are given on the first line for A and on the second for B molecule respectively.

labelling them A and B. The bond lengths and angles are given in Fig. 2. The standard deviations of bond lengths and angles involving sulfur atom have average values of $\pm 0.006 \text{ \AA}$ and $\pm 0.3^\circ$ respectively. The average standard deviations of bond lengths and angles are $\pm 0.01 \text{ \AA}$ and $\pm 0.6^\circ$ respectively, and are not shown separately.

Two benzene rings are planar within experimental error (see Table 3.). The S and N(1) atoms of A molecule are slightly out of the

benzene plane. The C-C bond lengths in the benzene rings vary from 1.35 to 1.40 \AA with a mean value of 1.37 \AA . The C(4)-N(1) bond lengths of 1.37 \AA for A molecule and 1.36 \AA for B molecule, which are significantly shorter than the corresponding normal single bond length of 1.44 \AA and in good agreement with the values reported in sulfanilamides^{14~17}, show an appreciable amount of double bond character.

Bonding around the sulfur atom is distorted from the ideal tetrahedral. The bond lengths

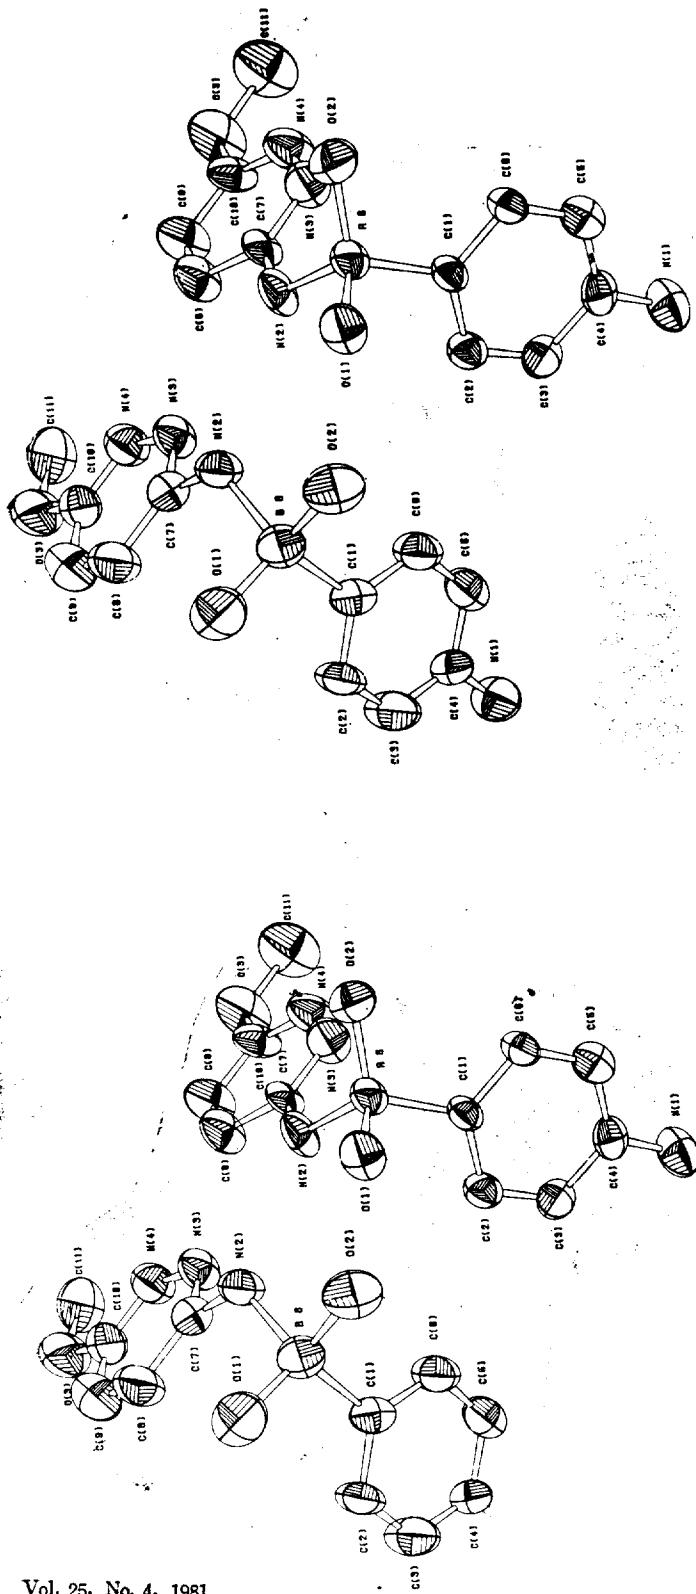

Fig. 1. ORTEP stereoscopic pair showing the molecular configuration of the sulfamethoxypyridazine with atomic numbering.

around the sulfur atom agree with the value reported in the related compounds.

The C(7)-N(2) bond lengths of 1.382 Å for A and 1.377 Å for B molecule indicate double bond character. Those double bond characters seem to be due to the conjugation of P_{π} electron on the nitrogen atom with the π -system of the pyridazine ring.

The six-membered pyridazine rings are almost planar (*Table 3*) and show the aromatic character. The N-N bond lengths of two molecules are same as 1.34 Å and are of the same order as the

length of similar bond in other pyridazine ring compound, e.g. 1.36 Å found by Cuckla and Smith¹⁸ in 6-amido-3-pyridazone. The N-C bond lengths range from 1.26 to 1.30 Å, which are close to the mean value between N-C double bond length of 1.21 Å in isocyanic acid¹⁹ and hybrid N-C bond length of 1.37 Å in pyridine²⁰. Similar N-C bond lengths have been found in 2-amino-4,6-dichloropyrimidine²¹ and 4-amino-2,6-dichloropyrimidine.²² The C(8)-C(9) bond lengths are significantly shorter than C(7)-C(8) and C(9)-C(10) bond lengths in both molecules.

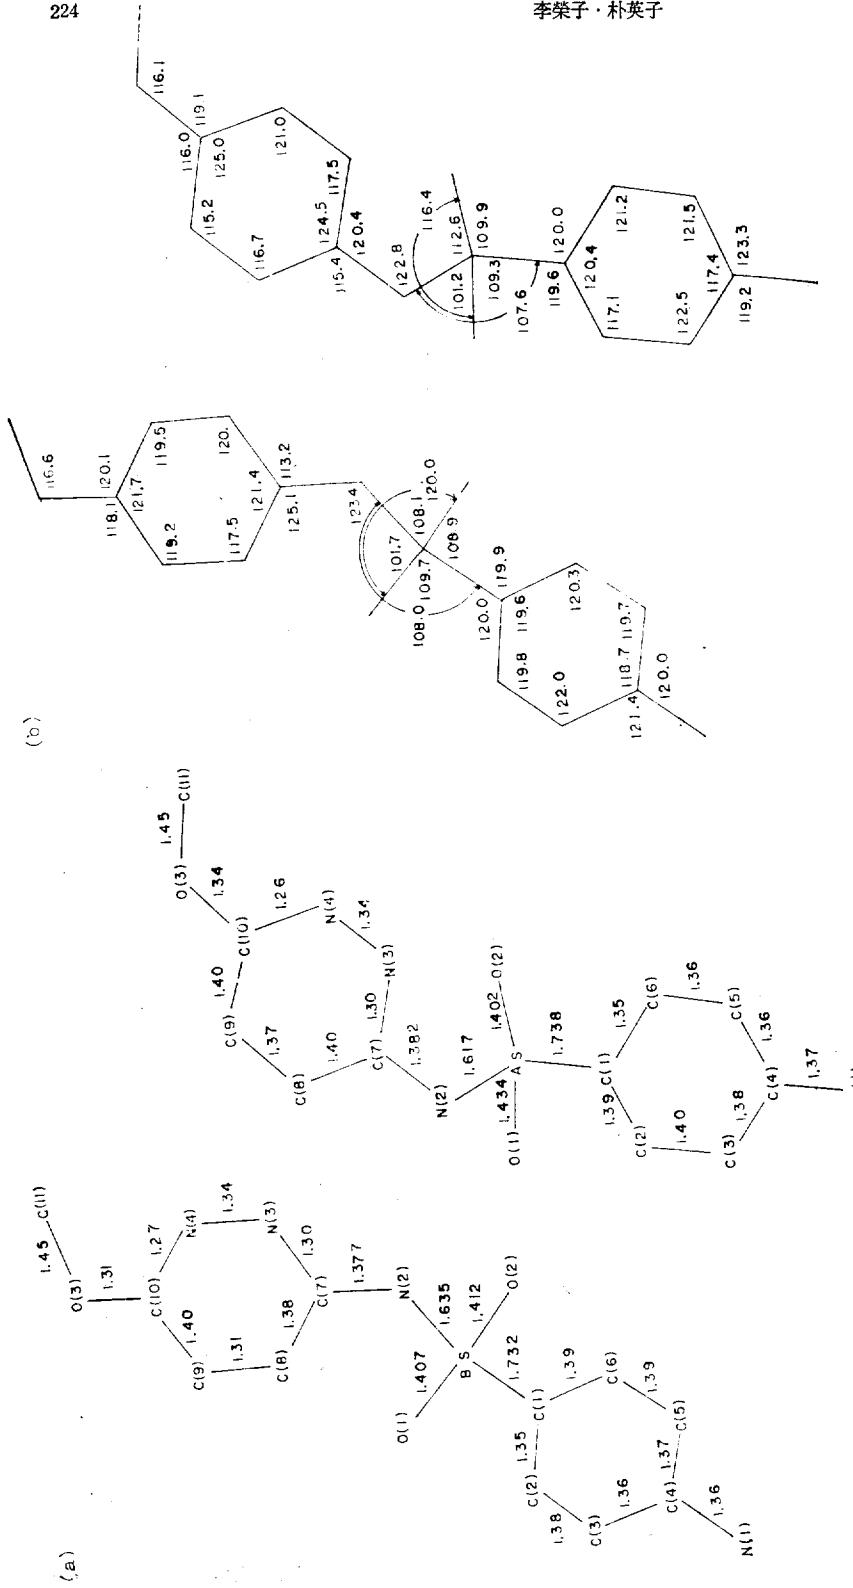

Fig. 2. Bond lengths and angles of sulfamethoxyridazine. (a) bond lengths (\AA), (b) valence angles ($^\circ$).

The bond lengths and angles in the methoxy groups are similar to those of sulfadimethoxine.

forms with different direction; Torsion angles are -66.6° for A and 58.5° for B molecule respectively. The benzene and pyridazine ring planes make the angle of 89.2° for A and 77.0° for B molecule respectively. The conformational angles of C(1)-S-N(2)-C(7) in related compounds are compared in Table 5.

* The thiazole ring is not aromatic. **The calculation of conformational angle from the reported coordinates does not give any proper value.

with the angles between the two aromatic planar rings in these compounds. As shown in Table 5, the molecules in these compounds maintain *gauche* forms with torsion angles in the range

of 54° to 80° and two rings are almost perpendicular to each other with mean interplanar angle of 85° . These differences of the conformation and interplanar angles may be attributed to different hydrogen bonding schemes and different molecular environments in these compounds.

The crystal structure of sulfamethoxypyridazine is shown in Fig. 4. All amino and imino hydrogen atoms are involved in six hydrogen bonds as all donors with distances in the range of 2.82 to 3.21 Å (see Fig. 3). Both N(1) atoms of the amino groups of A and B molecules participate in four hydrogen bonds with oxygen atoms; N(1A)H...O(1A)a, N(1A)H...O(3B)b, N(1B)H...O(1B)c and N(1B)H...O(2B)a. The molecules A and B are connected each other through two strong hydrogen bonds involving imino hydrogen atoms, one is N(2A)H...N(3B) with N...N distance of 2.84 Å and the other N(2B)H...O(1A) with N...O distance of 2.82 Å. The oxygen atom O(1A) is thus bonded to two different hydrogen bonds with N(1A) and N(2B) respectively. Atoms O(2A), O(3A), N(3A),

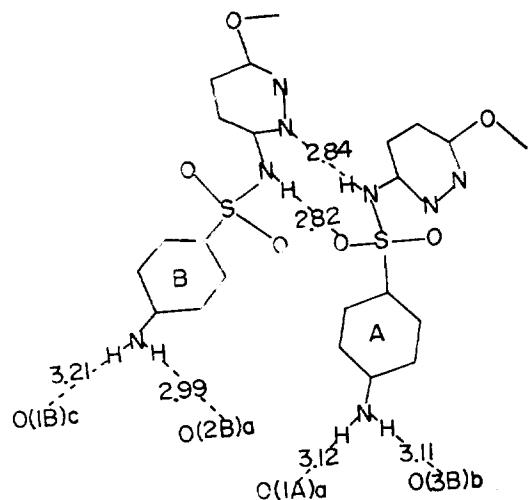

Fig. 3. The hydrogen bonding in sulfamethoxypyridazine. symmetry code : (a) $x-1, y, z$; (b) $x-1, y-1, z$; (c) $-x+1, y-0.5, -z+0.5$.

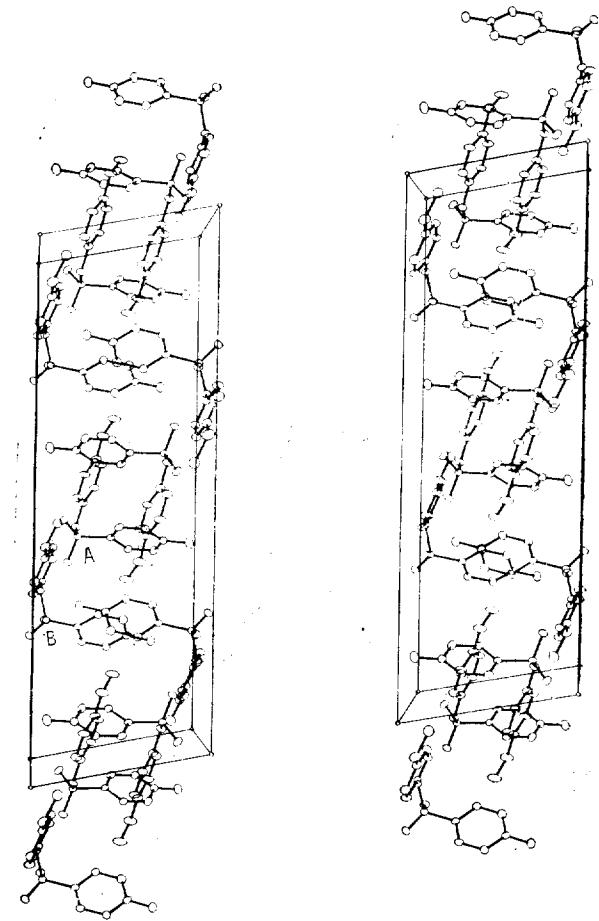

Fig. 4. The crystal structure of sulfamethoxypyridazine, origin in the remote lower right corner, α pointing to the left, c up and b forward. The reference molecules (Table 2) are indicated.

$N(4A)$ and $N(4B)$ do not take part in any hydrogen bonds.

Apart from the hydrogen bonds, the molecules are held together by the van der Waals interactions. There are 28 intermolecular atomic distances less than 3.5 Å.

The authors wish to thank Professor G. A. Jeffrey and members of Department of Crystallography, University of Pittsburgh for their help and allowing us to use their computing facilities. We also thank Professor C. H. Koo,

Department of Chemistry, Seoul National University in which the early portion of the work were carried out.
